Session	2026-27 (ODD)	Course Name	PE-V : Lab : Blockchain Technology
Semester	7	Course Code	23IOT1748
Roll No	61	Name of Student	Sheikh Wasimuddin

Practical Number	05
Course Outcome	1. Demonstrate basics of distributed systems and cryptographic primitives used in blockchain. 2. Outline various research aspects for development of blockchain. 3. Make use of different security protocols to build secure blockchain applications. 4. Analyze smart contracts and Hyperledger Fabric used in blockchain. 5. Determine the performance of applications developed with Bitcoin and Ethereum blockchain.
Aim	Implement Solidity Programs Using Variables, Data Types, Operators, Functions, Conditional Statements, and Loops.
Problem Statements	1. Student Result Smart Contract Create a smart contract that: • Stores student information • Stores marks in three subjects • Calculates total marks • Calculates the average • Determines pass / fail 2. Electricity Bill Calculator Create a smart contract that calculates an electricity bill based on units consumed. • Store: Customer Name, Customer ID, Units Consumed • 0 – 100 units → ₹5 per unit • 101 – 200 units → ₹7 per unit • Above 200 units → ₹10 per unit • Write a function to calculate the total bill using conditional statements.
Theory (100 words)	Solidity is a programming language designed for developing smart contracts on blockchain platforms such as Ethereum. It is a high-level, statically typed language that allows developers to write programs for managing digital assets, storing information, and implementing decentralized applications.

Department of Computer Science & Engineering (IoT)

Vision of the Department

To be a well-known centre for pursuing computer education through innovative pedagogy, value-based education and industry collaboration.

Mission of the Department

To establish learning ambience for ushering in computer engineering professionals in core and multidisciplinary area by developing Problem-solving skillsthrough emerging technologies.

Solidity programs are compiled into bytecode and executed by the Ethereum Virtual Machine (EVM).

1. Variables and Data Types

Variables are used to store and manage information in a smart contract. Solidity provides different data types according to the nature of the data.

- uint: Stores unsigned integer values.
- int: Stores signed integer values.
- bool: Stores either true or false.
- string: Stores text.
- address: Stores an Ethereum account or contract address.

Variables may be declared as state variables, which retain their values on the blockchain, or local variables, which are used temporarily during function execution.

2. Operators

Operators are used to perform calculations, comparisons, and logical operations in Solidity.

- Arithmetic operators: +, -, *, /, %
- Comparison operators: ==, !=, >, <, >=, <=
- Logical operators: &&, ||, !
- Assignment operators: =, +=, -=, *=

Operators help smart contracts perform mathematical calculations, compare values, and make decisions based on conditions.

3. Functions

Functions are blocks of code that perform specific tasks in a smart contract. They can accept input parameters and return results. Functions are used to read or modify contract data and implement the main operations of a decentralized application.

Solidity provides different visibility levels:

- public: Can be accessed internally and externally.
- private: Can be accessed only within the same contract.
- internal: Can be accessed within the contract and derived contracts.

Department of Computer Science & Engineering (IoT)

Vision of the Department

To be a well-known centre for pursuing computer education through innovative pedagogy, value-based education and industry collaboration.

Mission of the Department

To establish learning ambience for ushering in computer engineering professionals in core and multidisciplinary area by developing Problem-solving skillsthrough emerging technologies.

	- external: Can be called from outside the contract. Functions can also be declared as view when they only read blockchain state, or pure when they do not read or modify blockchain state. 4. Conditional Statements Conditional statements allow a smart contract to execute different instructions depending on whether a condition is true or false. Solidity mainly supports if, else if, and else statements. For example, a contract can check whether a student's marks are greater than or equal to 40 and return Pass; otherwise, it returns Fail. Conditional statements are useful for implementing rules, validating inputs, and controlling the execution of contract functions. 5. Loops Loops are used to execute a block of code repeatedly. Solidity supports the following loops: - for loop: Used when the number of iterations is known. - while loop: Executes as long as a specified condition remains true. - do-while loop: Executes the block at least once before checking the condition. Loops can be used for tasks such as calculating sums, processing arrays, and finding factorials. However, excessive use of loops should be avoided because blockchain computation consumes gas, which can increase transaction costs.
Procedure and Execution (100 Words)	A. Student Result Smart Contract Implementation Steps: 1. Open Remix IDE and create a new Solidity file named StudentResult.sol. 2. Specify the Solidity compiler version using the pragma statement. 3. Create a smart contract named StudentResult. 4. Declare variables to store the student name, student ID, and marks in three subjects. 5. Create a function to enter and store the student information and marks.

Department of Computer Science & Engineering (IoT)

Vision of the Department

To be a well-known centre for pursuing computer education through innovative pedagogy, value-based education and industry collaboration.

Mission of the Department

To establish learning ambience for ushering in computer engineering professionals in core and multidisciplinary area by developing Problem-solving skillsthrough emerging technologies.

6. Create a function to calculate the total marks by adding the marks of all three subjects.
7. Create a function to calculate the average marks using the formula:
$$\text{Average} = \text{Total Marks} / 3$$
8. Use conditional statements to determine the result:
 - o $\text{Average} \geq 40 \rightarrow \text{Pass}$
 - o $\text{Average} < 40 \rightarrow \text{Fail}$
9. Create a function to display the student information, total marks, average, and result.
10. Compile the smart contract using the Solidity Compiler in Remix IDE.
11. Deploy the smart contract using the Deploy & Run Transactions option.
12. Enter the student's details and marks.
13. Call the calculation functions and verify the total marks, average marks, and pass/fail result.

B. Electricity Bill Calculator

Implementation Steps:

1. Open Remix IDE and create a new Solidity file named ElectricityBill.sol.
2. Specify the Solidity compiler version using the pragma statement.
3. Create a smart contract named ElectricityBill.
4. Declare variables to store the customer name, customer ID, and units consumed.
5. Create a function to enter and store the customer details and units consumed.
6. Create a function named calculateBill() to calculate the electricity bill.
7. Use conditional statements to determine the electricity rate:
 - o 0–100 units $\rightarrow$ ₹5 per unit
 - o 101–200 units $\rightarrow$ ₹7 per unit
 - o Above 200 units $\rightarrow$ ₹10 per unit
8. Calculate the total bill using the selected rate and units consumed.
9. Create a function to display the customer details and total bill.
10. Compile the smart contract using the Solidity Compiler in Remix IDE.
11. Deploy the smart contract using the Deploy & Run Transactions option.
12. Enter the customer details and units consumed.
13. Call the calculateBill() function and verify the total electricity bill.

The screenshot shows the Remix IDE interface. On the left, the 'Environment' panel shows a 'Remix VM' with 'Osaka' as the network and 'Account 1' with a balance of 99.999 ETH. The 'Deployed Contracts' panel shows a contract named 'StudentResult' deployed at '0xBe...9fBe8'. The 'Functions' panel shows a list of functions: 'total', 'average', and 'result'. The 'total' function is selected, and the 'Call' button is visible. The main editor shows the Solidity code for the 'StudentResult' contract, which includes variables for name, id, and marks, and functions for calculating total marks, average marks, and a result based on the average.

This screenshot is similar to the one above, but it shows the 'result' function selected in the 'Functions' panel. The 'Call' button is still visible. The main editor shows the same Solidity code. The 'result' function is a public view function that returns a string memory, which is either 'PASS' or 'FAIL' based on the average marks.

Mission of the Department

To establish learning ambience for ushering in computer engineering professionals in core and multidisciplinary area by developing Problem-solving skillsthrough emerging technologies.

	
Conclusion	The practical successfully demonstrated the implementation of two Solidity smart contracts, StudentResult and ElectricityBill, using Remix IDE. The StudentResult contract showed how student details and marks can be stored, total and average marks can be calculated, and the result can be determined

	using conditional statements. The ElectricityBill contract demonstrated how customer details and units consumed can be stored and how the electricity bill can be calculated using different unit rates. Both contracts were compiled and deployed successfully, and their functions were executed to verify the results. The practical helped in understanding Solidity variables, functions, operators, conditional statements, and the basic process of developing and deploying smart contracts on the Ethereum blockchain.
